

Why sequence models

Examples of sequence data

Speech recognition		→	
Music generation		→	
Sentiment classification	"There is nothing to like in this movie."	→	★☆☆☆☆
DNA sequence analysis	AGCCCCTGTGAGGAACTAG	→	AGCCCCTGTGAGGAACTAG
Machine translation	Voulez-vous chanter avec moi?	→	Do you want to sing with me?
Video activity recognition		→	Running
Name entity recognition	Yesterday, Harry Potter met Hermione Granger.	→	Yesterday, <u>Harry Potter</u> met <u>Hermione Granger</u> .

- Can be addressed as supervised learning problems
- In some, both the input X and the output Y are sequences, and in that case, sometimes X and Y can have different lengths,
- In some of these examples only either X or only the opposite Y is a sequence.

Named entity recognition: Identify names, times, locations etc in a sequence (used by search engines)

How would we frame X and y?

x: Harry Potter and Hermione Granger invented a new spell.

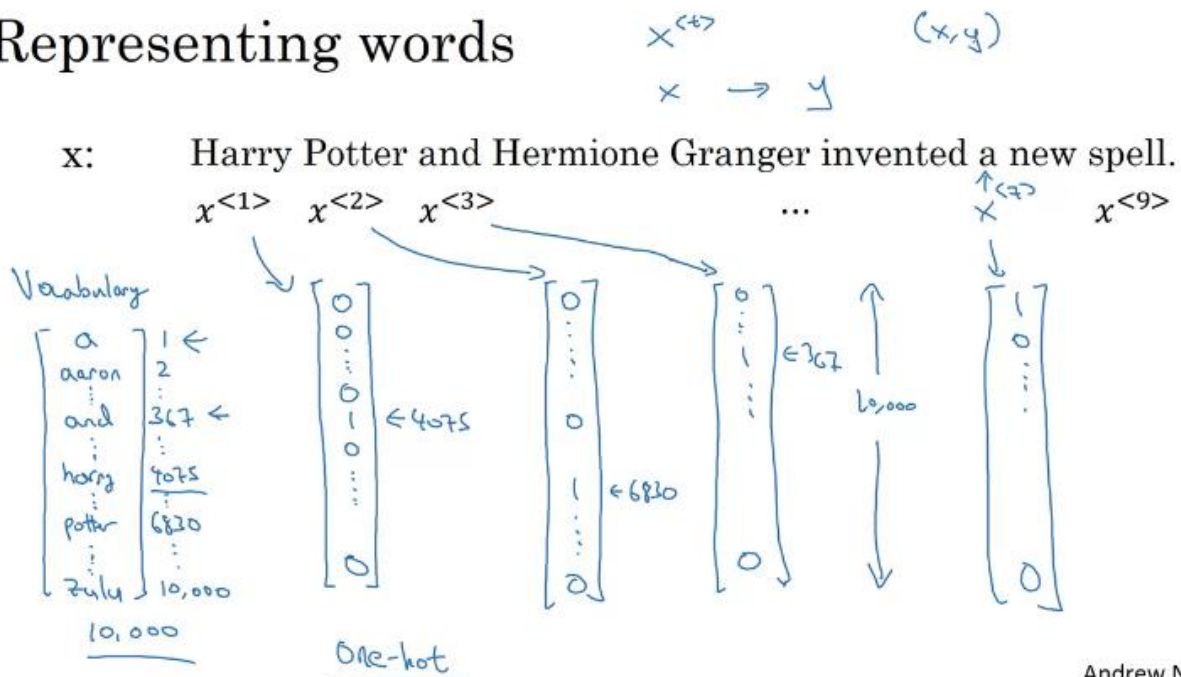

y: 1 1 0 1 1 0 0 0 0

Maybe the above isn't the best output representation, there are some more sophisticated output representations that tell you not just whether a word is part of a person's name, but tell you where are the start and ends of people's names in the sentence.

Now let's index the position of each word and its label, because these are temporal sequences.

$\rightarrow y:$

1	1	0	1	1	0	0	0	0
$y^{(1)}$	$y^{(2)}$	$y^{(3)}$						$y^{(9)}$

RNN

Why not a standard network?

Problems:

- Inputs, outputs can be different lengths in different examples.
- Doesn't share features learned across different positions of text.

Problems:

1. Inputs and outputs can be different lengths for different examples. Maybe we could identify the maximum length of a sentence, and pad other smaller sentences upto that length, but this still wouldn't look like a good representation
2. Doesn't share features learned across different positions of texts. e.g. if the NN figures out that the word Harry appearing in position 1 is a sign that it is a person's name, it would be nice if it could automatically figure out that Harry appearing in another position is also a name. This is similar to CNN where we'd like things learnt in one part of an image to generalize well to other parts of the image as well.

An RNN addresses both these limitations

What is an RNN?

Recurrent Neural Networks

In the above, we first predict $y^{(1)}$ by feeding the first word $X^{(1)}$ into an NN layer. Then we read the second word $X^{(2)}$, and also use some information from what was computed at 1st step, to predict $y^{(2)}$.

In this architecture, T_x and T_y are identical, i.e. input and output sequence lengths are the same.

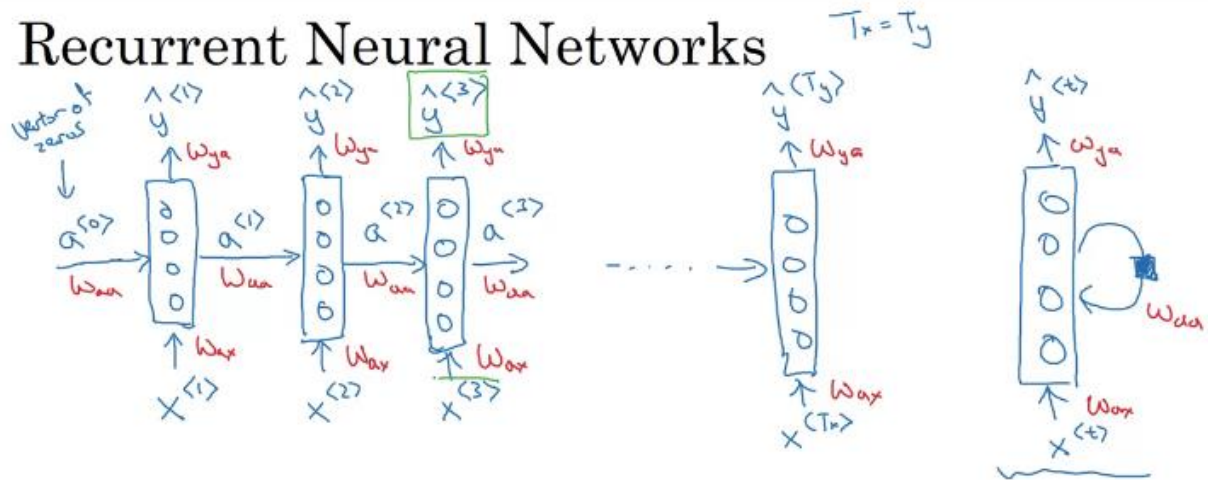

We also add a vector of activations at time 0, usually a vector of 0s.

At every time step:

1. W_{ax} (parameters governing connection from X to hidden layer) are identical
2. W_{aa} (parameters governing horizontal connections) are identical
3. W_{ya} (parameters governing output predictions) are identical

Recurrent Neural Networks

So prediction $y^{(3)}$ uses info from not only $X^{(3)}$ but also $X^{(1)}$ and $X^{(2)}$

Recurrent Neural Networks

Drawback: Doesn't use $X^{(4)}, X^{(5)}$ etc i.e. later words in the sentence.

In below sentence, not possible to decide whether Teddy is part of a person's name by **just** looking at the first three words.

He said, "Teddy Roosevelt was a great President."

He said, "Teddy bears are on sale!"

Andrew Ng

Later in this course: Bidirectional RNNs (BRNNs) address this

Forward propagation

Forward Propagation $a \leftarrow W_{ax} x^{(i)}$

Simplified RNN notation

$$a^{(t)} = g(W_{aa} a^{(t-1)} + W_{ax} x^{(t)} + b_a)$$

Dimensions: $(100, 100) \times 100 + (100, 10,000) \times 10,000 + 100$

$$\hat{y}^{(t)} = g(W_{ya} a^{(t)} + b_y)$$

$$a^{(t)} = g(W_a [a^{(t-1)}, x^{(t)}] + b_a)$$

Dimensions: $(100) \times [100, 10,000] = W_a (100, 10,100)$

$$[a^{(t-1)}, x^{(t)}] = \begin{bmatrix} a^{(t-1)} \\ x^{(t)} \end{bmatrix}$$

Dimensions: $\begin{matrix} 100 \\ 10,000 \end{matrix} \rightarrow 10,100$

$$[W_{aa}; W_{ax}] \begin{bmatrix} a^{(t-1)} \\ x^{(t)} \end{bmatrix} = W_{aa} a^{(t-1)} + W_{ax} x^{(t)}$$

See my handwritten notes for the math

Backpropagation through Time

Forward propagation and backpropagation

Types of RNN

Examples of sequence data

Speech recognition

"The quick brown fox jumped over the lazy dog."

Music generation

∅

Sentiment classification

"There is nothing to like in this movie."

DNA sequence analysis

AGCCCCTGTGAGGAACTAG

AGCCCCTGTGAGGAACTAG

Machine translation

Voulez-vous chanter avec moi?

Do you want to sing with me?

Video activity recognition

Running

Name entity recognition

Yesterday, Harry Potter met Hermione Granger.

Yesterday, **Harry Potter** met **Hermione Granger**.

Andrew Ng

Many to many

$$T_x = T_y$$

Many-to-many

Many to one

Sentiment classification

Sentiment classification:-

$x = \text{text}$

$y = 0/1 \quad 1 \dots 5$

Many-to-one

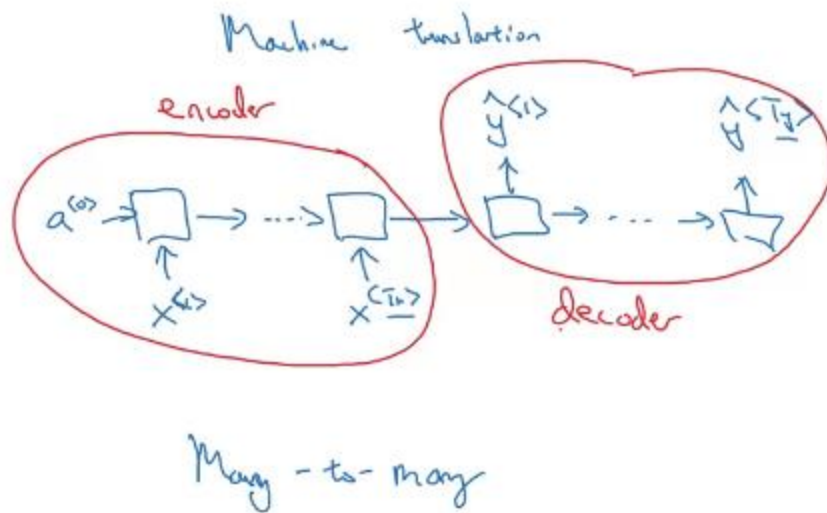

One to one

One to many
Music generation

Many to many with different input and output lengths
e.g. machine translation

Summary of RNN types

Andrew Ng

Language model & sequence generation

Estimates the probability of that particular sequence of words.

What is language modelling?

Speech recognition

The apple and pair salad.

→ The apple and pear salad.

$$P(\text{The apple and pair salad}) = 3.2 \times 10^{-13}$$

$$P(\text{The apple and pear salad}) = 5.7 \times 10^{-10}$$

$$P(\text{Sentence}) = ?$$

$$P(y^{(1)}, y^{(2)}, \dots, y^{(T)})$$

First we tokenize the sentence, and one-hot encode

We also add a token for end-of-sentence

Language modelling with an RNN

Training set: large corpus of english text.

Tokenize

Cats average 15 hours of sleep a day. \downarrow $\langle \text{EOS} \rangle$

$y^{(1)}$ $y^{(2)}$ $y^{(3)}$... $y^{(8)}$ $y^{(9)}$

The Egyptian ~~Mau~~ is a breed of cat. $\langle \text{EOS} \rangle$

10,000

$\langle \text{UNK} \rangle$

Sampling novel sequences

Sequence models model the chance of any particular sequence of words, so what we like to do is sample from this distribution to generate novel sequences of words.

At the first timestep, we sample from the vocabulary of our words using softmax function.

At the second timestep, we pass in the sampled word from the first timestep as an input i.e. $x^{<2>} = y^{<1>}$.

And so on till end of all timesteps.

Sampling a sequence from a trained RNN

We can also build a character level RNN

Character-level language model

Vocabulary = [a, aaron, ..., zulu, <UNK>]

Vocabulary = [a, b, c, ..., z, \backslash , ., , , ;, 0, ..., 9, A, ..., Z]

Pros:

1. Don't have to worry about unknown word tokens

Cons

1. End up with much longer sequences
2. Computationally expensive

Sequence generation

News

President enrique peña nieto, announced
sench's sulk former coming football langston
paring.

"I was not at all surprised," said hich langston.

"Concussion epidemic", to be examined.

The gray football the told some and this has on
the uefa icon, should money as.

Shakespeare

The mortal moon hath her eclipse in love.

And subject of this thou art another this fold.

When besser be my love to me see sabl's.

For whose are ruse of mine eyes heaves.

Vanishing gradients with RNN

We should match 'cats' with 'were' and 'cat' with 'was'.

But basic RNNs are not good at capturing long term dependency.

The cat which already ate was full
 The cats wh were full

Outputs have local influences, ie values closer in the sequence

Recall that for exploding gradients, we use gradient clipping.

Gated Recurrent Units (GRU)

Helps capture long term dependencies

Below is the visualization of the RNN unit of the hidden layer of the RNN

RNN unit

GRU units will have a new variable C which is a memory cell

At every timestep, $\tilde{C}^{(t)}$ will be a candidate value for replacing the memory cell

$$\begin{aligned} C &= \text{memory cell} \\ \underline{C}^{(t)} &= \underline{a}^{(t)} \\ \tilde{C}^{(t)} &= \tanh(W_c[C^{(t-1)}, x^{(t)}] + b_c) \end{aligned}$$

The important idea of GRU is a gate, Γ_u where the u refers to update. Can think of it as always 0 or 1, though computed by sigmoid function.

The new $C^{<t>}$ will be Γ_u times the candidate value, plus $1 - \Gamma_u$ times the old value.

So when Γ_u is 1, we update to candidate value. If 0, then don't update, hang on to old value.

$$C^{<t>} = \Gamma_u \times \hat{C}^{<t>} + (1 - \Gamma_u) \times C^{<t-1>}$$

The purple box above is just

So the word 'cat' is read early in the sentence, so the update gate is set to 1, and then is not updated at successive. Finally it gets used to decide the word "was"

With tiny value of Γ_u , the previous value of C_t basically continues to persist without any update.

Full GRU

$$\tilde{h} \quad \tilde{c}^{<t>} = \tanh(W_c[\underbrace{\Gamma_r}_{\text{LSTM}} * c^{<t-1>}, x^{<t>}] + b_c)$$

$$u \quad \Gamma_u = \sigma(W_u[c^{<t-1>}, x^{<t>}] + b_u)$$

$$r \quad \Gamma_r = \sigma(W_r[c^{<t-1>}, x^{<t>}] + b_r)$$

$$h \quad c^{<t>} = \Gamma_u * \tilde{c}^{<t>} + (1 - \Gamma_u) * c^{<t-1>}$$

LSTM

The cat, which ate already, was full.

LSTM
